License Validation Flow

License Validation Flow

A protected resource validates against the Nord Forge licensing API.

The validation checks:

1. The Forge Key exists and belongs to an active account.
2. The product can be resolved.
3. The product is assigned to the customer.
4. The product license is active.
5. The license has not expired.
6. The FiveM Keymaster is registered and active.
7. The Keymaster belongs to the same Forge customer.

Session validation

Protected builds can request a temporary session used to unlock protected runtime code.

The current backend returns:

- A temporary decryption key
- A session TTL
- A heartbeat interval
- Release update information
- Active server slot information

Revoking or suspending product access causes later validation/session requests to fail.
